

Experiment-3.

Aim:- To study the position control of the DC servomotor.

Apparatus: Motor unit, control unit.

Theory: Motor Unit: • It consists of permanent magnet armature controlled geared servo motor. It has technical specification as:

Voltage: 12Vdc, 5W; Rated Shaft Speed: 50 RPM

Torque: 3.5kg/cm at load shaft.

The angular displacement is sensed by a 360° servo potentiometer.

Control Unit: This unit has reference servo potentiometer, source voltage, error detector, amplifier, motor driver circuit, a RAM card & necessary regulated supplies for the circuit. The details of the control is given below:

1° Command Signal:- There are 2 command signals are provided in the control unit. One is the continuous command signals are provided in the control unit.

2° Error Detector: It is a four & one output block, two of them are positive oriented for command signal and two negative oriented for feedback.

The output of this block is:

$$e_c = e_{c1} + e_{c2} + (-ef1 + ef2).$$

SYSTEM REPRESENTATION IN BLOCK DIAGRAM.

3. Gain Blocks: There are two gain settings provided upon the panel. One block provided forward path gain K_A in equal steps from 3 to 10, selected by rotary switch provided upon the panel.

4. Motor driver block: The driver unit gain equal to one & is in form of complementary push pull stage to run the motor in either direction.

5. Waveform capture / display block: The time response of the system is too slow for convenient display on CRO.

6. DVM: A $3\frac{1}{2}$ digit digital voltmeter is provided to take reading of command & feedback voltages.

Procedure:

1. Connect motor unit with the control unit.
Set tacho feedback = 0.
2. Switch on the power. Set $K_A = 3$.
3. Starting from one end say 30° , move command potentiometer in steps of 30° approximately upto 300° .

Result: As the value of gain increases, the % Error will decrease.
